EXCEL ANALYTICS / PORTFOLIO CASE STUDY

SYNTHETIC DATA

Holiday Yield Management

Destination performance, booking momentum and pricing trade-offs

Objective: analyse a simulated holiday-booking dataset to identify destinations requiring review, compare pricing against competitors, and evaluate a simple discount decision.

SEATS SOLD	AVAILABLE SEATS	OVERALL LOAD FACTOR
8,789	17,300	50.8%

DESTINATION PERFORMANCE

Aggregate figures across simulated departure weeks

DESTINATION	LOAD FACTOR	WEEKLY CHANGE	SEATS LEFT	VS. MARKET
Antalya	51.6%	-0.53%	1,424	+0.37%
Lisbon	49.9%	-14.76%	1,487	+0.56%
Malaga	43.4%	+4.95%	1,646	-0.23%
Marrakech	53.3%	-4.22%	1,337	+0.77%
Rome	49.2%	-20.28%	1,477	-0.05%
Tenerife	57.8%	-5.80%	1,140	+6.09%

THREE FINDINGS

01 **ROME - REVIEW**

49.2% load factor; weekly bookings down 20.28% despite near-market pricing. Review departure timing and changes in demand.

02 **LISBON - REVIEW**

49.9% load factor and bookings down 14.76%. Investigate booking pace, seasonality and competitor package comparability.

03 **MALAGA - WATCH**

Lowest load factor (43.4%) but the only positive booking change (+4.95%); avoid assuming a discount is needed.

PRICING SCENARIO: IS A 5% DISCOUNT WORTH IT?

Illustrative assumption: variable cost is £500 per booking.

KEEP £800	DISCOUNT TO £760	BREAK-EVEN TEST
£6,000	£5,720	24 bookings
20 bookings	22 bookings	needed to improve

COMMERCIAL RECOMMENDATION

Maintain the £800 price in this simple scenario: selling 22 discounted packages yields £280 less contribution than selling 20 at full price. For Rome and Lisbon, investigate departure-level trends before testing targeted price changes; monitor the impact on contribution, not bookings alone.

METHOD

Excel PivotTables, calculated KPIs, XLOOKUP, conditional formatting, charts and an assumed-price scenario.

Limitations: all booking figures are fictional. Market prices are averaged across departure weeks; no causal impact or real demand elasticity has been established.
